- Also collaborating extensively with S. Louie's and Martin Head-Gordon's groups

Outline

Motivation

2 Scalability

- Self-Consistent Field
- Linear Scaling Methods

3 Robustness

- Direct Constrained Minimization
- Ease of UseKSSOLV

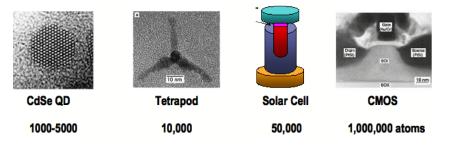

5 Summary and Future Work

Advances in density functional theory coupled with multinode computational clusters now enable accurate simulation of the behavior of multithousand atom complexes that mediate the electronic and ionic transfers of solar energy conversion. These new and emerging nanoscience capabilities bring a fundamental understanding of the atomic and molecular processes of solar energy utilization within reach.

Basic Research Needs for Solar Energy Utilization Report of the BES Workshop on Solar Energy Utilization April 18-21, 2005

Large-scale electronic structure calculations

- Nanosystems often involve 1000-1,000,000 atoms
- Atomic details are still important: surface charge, impurities, dopant, symmetry, passivation
- Materials by design could potentially be accelerated through the judicious use of computational and mathematical tools

A (1) > A (1) > A

Kohn-Sham Density Functional

• Kohn-Sham total energy

$$E_{total}[\{\psi_i\}] = \frac{1}{2} \sum_{i=1}^{n_e} \int_{\Omega} |\nabla \psi_i|^2 + \int_{\Omega} V_{ext}\rho + \frac{1}{2} \int_{\Omega} \frac{\rho(r)\rho(r')}{|r-r'|} dr dr' + E_{xc}(\rho)$$

where
$$\rho = \sum_{i=1}^{n_e} |\psi_i(r)|^2$$
, $\int_{\Omega} \psi_i \psi_j = \delta_{i,j}$.

Kohn-Sham equations

$$\left[-\frac{1}{2}\nabla^2 + V_{ext}(r) + \int \frac{\rho}{|r-r'|} + V_{xc}(\rho)\right]\psi_i = \epsilon_i\psi_i, \quad i = 1, 2, ..., n_e$$

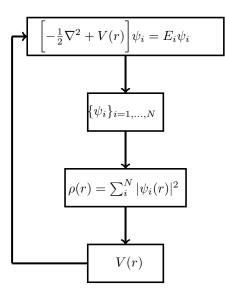

▲ @ ▶ ▲ ≥ ▶ ▲

Approaches for solving the Kohn-Sham Equations

- Work with the KS equations directly
 - Self-Consistent Field Iteration
 - Large-scale linear eigenvalue problem
 - Need to precondition
 - Use charge mixing for faster convergence
- Minimize the total energy directly
 - Direct Constrained Minimization
- Many other methods unfortunately we don't have the time to discuss them today

The SCF Iteration

- Memory $O(N^2)$
- Complexity $O(N^3)$
- Major work load
 - 3D FFT
 - Orthogonalization
 - Nonlocal potential

Scaling of conventional DFT methods

- DFT methods account for 75% of the material science simulations at NERSC, totaling over 5 million hours of computer time last year
- Parallelization can improve performance
 - $\bullet\,$ on plane wave basis can scale to ≈ 1000 processors
 - on plane wave basis and wavefunction index can scale to pprox 10,000 processors
- Parallel efficiencies can be quite high

So what's the problem?

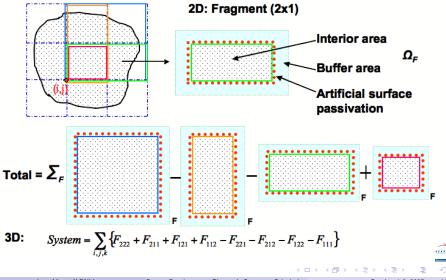

Algorithms scale as ${\cal O}(N^3)$; Would it be more efficient to use a linear scaling method for larger systems?

- Divide a large system into smaller sub-domains that can be solved independently, then stitch the sub-domains back together again
- Why might this work?
 - quantum mechanical effects are near-sighted, i.e. treat the quantum mechanical wavefunctions locally
 - classical electrostatic interactions are long-ranged, i.e. solve one global Poisson equation
- Requires minimal communication between the sub-domains
- Artificial boundary effects due to sub-dividing domains can be cancelled out
- Based on ideas from fragment molecular method
- We call our method Linear Scaling 3D Fragment or LS3DF ¹

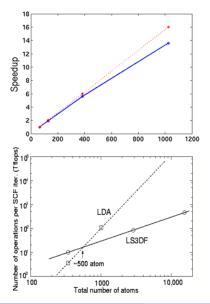

¹L.W. Wang, Z. Zhao, J. Meza, LBNL-61691 (2006)

Divide and conquer (pictorially)

Juan Meza (LBNL)

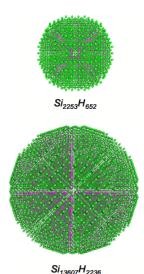

Scaling of LS3DF

- Almost linear speedup up to 1000 processors
- Cross over between LS3DF and direct LDA happens around 500 atoms
- LS3DF should scale well to petascale machines

Results for Si quantum dot

 LS3DF on 3000 atom quantum dot using 1024 processors at NERSC took 1 hour

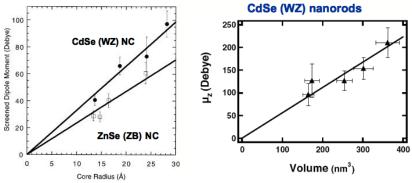

- A similar simulation using direct LDA would take several days
- LS3DF on 15,000 atom quantum dot using 2048 processors at NERSC took 5 hours
- A similar simulation using direct LDA would take a few months

Image: A = 10 million

Nanostructure Dipole Moment

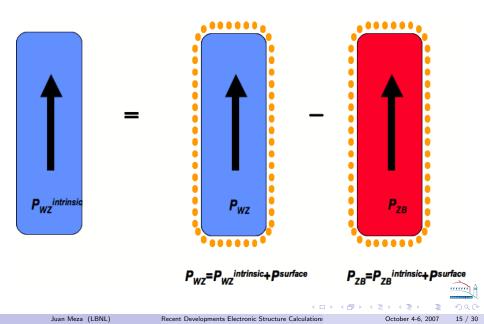

M. Sim, P. Guyot-Sionnet, JCP 111, 6955 (1999) L.

L. Li, A.P. Alivisatos, PRL 90, 097402 (2003)

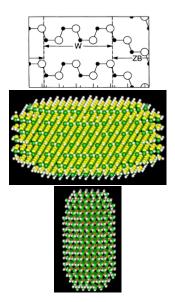

- What is the net dipole moment of ZnSe (ZB)?
- Is there a volume dependence?

Juan Meza (LBNL)

Removing the Surface Contribution

Geometric Effects on Dipole Moment

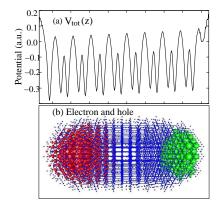

- Pure bulk contribution = $0.0143 \times (N_{Cd} + N_{Se})$
- $P_0 = 20.5(a.u.) (\approx 2500 \text{ atoms})$
- R = 7, L = 3 (a.u.), P = 30.3 (a.u.) \rightarrow effective screening
- R = 4.5, L = 9 (a.u.), P = 73.3 (a.u.) \rightarrow weak screening
- Dipole moment of this nanostructure has a strong geometry dependence

CdSe wurtzite quantum rods

- $Cd_{961}Se_{724}$ wurtzite quantum rods
- Used experimental crystal structures
- Top figure depicts potential along the central axis
- Bottom figure depicts the electron (red) and hole states (green) isosurfaces
- Electrons and holes are localized on opposite ends indicating internal electric field

Juan Meza (LBNL)

When can we expect SCF to work?

Juan Meza (LBNL)

• SCF does not always converge;

$$\begin{split} \lim_{i \to \infty} \|H(x^{(i+1)}) - H(x^{(i)})\| &\neq 0, \\ \text{or} \quad \lim_{i \to \infty} \|\rho(x^{(i+1)}) - \rho(x^{(i)})\| &\neq 0 \end{split}$$

• For some problems, we can show subsequence convergence;

$$\lim_{i \to \infty} \|\rho(x^{(i+1)}) - \rho(x^{(i-1)})\| = 0$$

• E(x) may not decrease in SCF

Why does SCF fail?

- SCF is attempting to minimize a sequence of surrogate models
- Objective:
 - $E(x) = \frac{1}{2}x^T L x + \frac{\alpha}{4}\rho(x)^T L^{-1}\rho(x)$ • $E_{sur}(x) = \frac{1}{2}(x^T H(x^{(i)})x),$
- Gradient:
 - $\nabla E(x) = H(x)x$
 - $\nabla E_{sur}(x) = H(x^{(i)})x$

Gradients match

 $\nabla E(x^{(i)}) = \nabla E_{sur}(x^{(i)})$

- Construct better surrogate
 - Cannot afford to use local quadratic approx (Hessian too expensive)
 - Charge mixing to minimize lack of self consistency (heuristic)
- Use Trust Region to restrict the update of the x in a small neighborhood of the gradient matching point
- TRSCF (Thogersen, Olsen, Yeager & Jorgensen 2004 Yang, Meza & Wang 2007)

- Assume $x^{(i)}$ is the current approximation
- Idea: minimize the energy in a certain subspace

• Update
$$x^{(i+1)} = \alpha x^{(i)} + \beta p^{(i-1)} + \gamma r^{(i)}$$
;

•
$$p^{(i-1)}$$
 previous search direction;

$$r^{(i)} = H^{(i)}x^{(i)} - \theta^{(i)}x^{(i)}$$

 $\bullet\,$ choose $\alpha,\,\beta$ and γ so that

•
$$x_{k+1}^T x_{k+1} = 1;$$

•
$$E(x_{k+1}) < E(x_k);$$

Direct Constrained Minimization²

Algorithm

Input: Initial guess $X^{(0)} \in \mathbb{C}^{n \times n_e}$, pseudopotential etc; Output: X such that $E_{KS}(X)$ is minimized

1
$$P^{(0)} = [], i = 0;$$

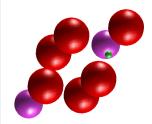

$$\begin{aligned} & \textbf{ while (not converged)} \\ & \textbf{ } \Theta^{(i)} = X^{(i)*}H^{(i)}X^{(i)}; \\ & \textbf{ } R^{(i)} = H^{(i)}X^{(i)} - X^{(i)}\Theta^{(i)}; \\ & \textbf{ } Set \ Y = (X^{(i)}, P^{(i-1)}, K^{-1}R^{(i)}); \\ & \textbf{ } Solve \min_{G^*Y^*YG=I_k} E_{tot}(YG); \\ & \textbf{ } X^{(i+1)} = YG(1:n_e,:); \ P^{(i+1)} = YG(n_e+1:3n_e,:); \\ & \textbf{ } i \leftarrow i+1; \end{aligned}$$

²C. Yang, J. Meza, L. Wang, A Constrained Optimization Algorithm for Total Energy Minimization in Electronic Structure Calculation, J. Comp. Phy., 217 (209-721) (2006)

Example: Pt_6Ni_2O

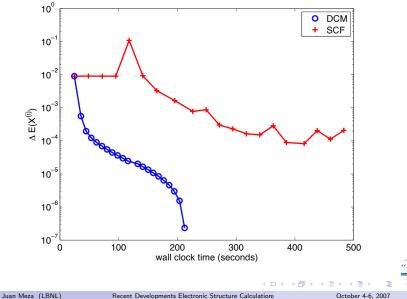

```
cell:
   19.59 0.0 0.0
   . . .
sampling size: n1 = 96, n2 = 48, n3 = 48
atoms and coordinates:
 1 Pt 1.3 -0.180 -0.015
 7 Ni 8.4 0.003 3.069
 8
   Ni 8.5 7.998 7.762
 9
      0 14.9 2.644 1.511
number of electrons : 86
                    : 1
spin type
kinetic energy cutoff: 60.0
```

Comparison of DCM vs. SCF

25 / 30

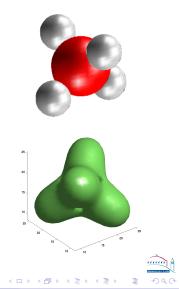

- KSSOLV Matlab code for solving the Kohn-Sham equations
- Open source package
- Handles SCF, DCM, Trust Region
- Example problems to get started with
- Object-oriented design easy to extend
- Good starting point for students

Beta version of KSSOLV available, ask one of us for more information!

Example: SiH_4

```
a1 = Atom('Si');
a2 = Atom('H');
alist = [a1 a2 a2 a2 a2];
xyzlist= [
0.0 0.0 0.0
1.61 1.61 1.61
...];
mol = Molecule();
mol = set(mol, 'Blattice', BL);
mol = set(mol, 'atomlist', alist);
mol = set(mol,'xyzlist', xyzlist);
mol = set(mol,'ecut', 25);
mol = set(mol, 'name', 'SiH4');
isosurface(rho);
```

Other work in our group

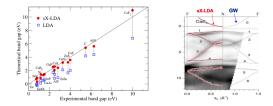

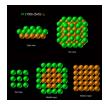

Figure: (left) band gap calcuations using screened exchange; (right) band gap for CaB_6

- New computational tools for modeling and simulation of nanosystems (large and small)
- Codes for large systems that scale linearly
- New algorithms that are potentially more robust than standard methods
- Rapid prototyping of new systems
- Tools can be used to hep explain (guide?) experimental results
